

# Human Proteome Project Data Interpretation Guidelines

## Version 2.0.0 - November 12, 2015

The following checklist is a brief summary of the full guidelines. This checklist must be completed by authors and submitted along with the manuscript. See pages 2-3 of this document for a more detailed description of each item in the checklist. Each item in the checklist must be either checked when deemed completed or marked as NA (Not Applicable). The checklist will be used by editorial staff and reviewers to guide their assessment of submissions, marking in their review if any of the guidelines are not completed to their satisfaction.

<b>General Guidelines:</b>	
√	1. Complete this HPP Data Interpretation Guidelines checklist and submit with the manuscript.
	2. Submit all MS proteomics data (DDA, SRM, DIA), including analysis reference files (search database, spectral library) to a ProteomeXchange repository as a complete submission and provide the PXD identifier(s) in the manuscript abstract.
	3. Perform informatics analysis against the most recent version of the neXtProt reference proteome, particularly with respect to which are missing proteins.
	4. Describe in detail how the FDRs at the PSM, peptide, and protein levels are calculated.
	5. Report the PSM-, peptide-, and protein-level FDR values along with the total number of expected true positives and false positives at each level.
	6. Present large-scale results thresholded at equal to or lower than 1% protein-level global FDR.
	7. Acknowledge that the protein-level FDR is an estimate based on several imperfect assumptions, and present the FDR with appropriate precision.
	8. Acknowledge that not all proteins surviving the threshold are “confidently identified”.
	9. If any datasets are individually thresholded and then combined, calculate the new, higher FDR for the combined result.
<b>Guidelines for extraordinary detection claims (e.g., missing proteins, novel coding elements)</b>	
	10. Present extraordinary detection claims based on DDA mass spectrometry with high-resolution, high signal-to-noise ratio (SNR), clearly annotated spectra.
	11. Consider alternate explanations of PSMs that appear to implicate extraordinary results.
	12. Present annotated spectra for extraordinary detection claims alongside high-resolution, high-SNR, clearly annotated spectra of synthetic peptides that match the putative identifications.
	13. If SRM verification for extraordinary detection claims is performed, present target traces alongside synthetic heavy-labeled peptide traces, demonstrating very closely matching elution time and intensity patterns.
	14. After very high confidence peptide identifications are demonstrated, consider alternate mappings of the peptides to proteins other than the claimed extraordinary result. Consider isobaric sequence/mass modification variants, all known SAAVs, and even unknown SAAVs.
	15. Support extraordinary detection claims by two or more distinct uniquely-mapping peptide sequences of length $\geq 9$ AA. When only lesser evidence is offered for an extraordinary protein or coding element detection, justify that other peptides cannot be expected.

Author comments (use this space to explain any NA markings or nonadherence in the above checklist):

## Extended Detail on Checklist items:

1. **Fill out this HPP Data Interpretation Guidelines checklist and submit with the manuscript.** Page 1 of this document must be submitted as supplementary material for the editor/reviewers. The completed checklist is required before a manuscript will be sent to reviewers. Each item in the checklist must be either checked or marked as NA (Not Applicable). Please explain NA entries or any other variances in the Author Comments section. Manuscripts received without a checklist will be returned without review.
2. **Submit all MS proteomics data (DDA, SRM, DIA) to a ProteomeXchange repository as a complete submission and provide the PXD identifier(s) in the manuscript abstract.** All submissions shall now be required to be “Complete” submissions instead of “Partial” submissions. ProteomeXchange submission may be delayed until after the initial submission is examined by the journal editors, but must be completed before the manuscript is sent to reviewers.
3. **Perform informatics analysis against the most recent version of the neXtProt reference proteome, particularly with respect to which are missing proteins.** Informatics analysis should always be presented in comparison with the most recent proteome references, rather than older versions thereof. For the 2016 HPP special issue, this is expected to be neXtProt version 2016-02 and PeptideAtlas version 2016-01.
4. **Describe in detail how the FDRs at the PSM, peptide, and protein levels are calculated.** Describe which tools are used to estimate the false discovery rate (FDR) at the peptide-spectrum-match (PSM) level, at the distinct peptide sequence level, and at the protein level. Briefly describe the approach and what assumptions are made or implied, and any corrections for the fraction of the proteome covered. If you use novel or uncommon tools and criteria, compare your results with results with tools that are widely used in the community.
5. **Report the PSM-, peptide-, and protein-level FDR values along with the total number of expected true positives and false positives at each level.** Report the actual numbers of true positives and false positives at each level based on the thresholds used.
6. **Present large-scale results thresholded at equal to or lower than 1% protein-level global FDR.** The 1% is somewhat arbitrary but well accepted and remains set as the upper limit. For many datasets from modern instrumentation, achieving a 1% global FDR may include very low quality results with a **local** FDR worse than 10%, which is undesirable. A global FDR lower than 1% is encouraged, but it should never be higher than 1%. Similarly, PSMs, peptides, and proteins with a local FDR worse than 10% should not be included.
7. **Recognize that the protein-level FDR is an estimate based on several imperfect assumptions, and present the FDR with appropriate precision.** For example if decoys are used to estimate the number of expected errors, realize that there other types of errors that are not modeled well by decoys, and therefore the calculated FDR may be considerably lower than the true FDR.
8. **Acknowledge that not all proteins surviving the threshold are “confidently identified”.** The common mistake of thresholding at 1% FDR and then assuming that all surviving results are correct, no matter how surprising, must be avoided. Sometimes the number of estimated false positives equals or exceeds the number of missing proteins claimed to be identified.
9. **If any datasets are individually thresholded and then combined, calculate the new, higher FDR for the combined result.** When datasets are combined, the true positives will mostly overlap, while the false positives will be scattered randomly across the proteome and thus overlap far less. This means that the FDR will be higher in the combined dataset.

10. **Present extraordinary detection claims based on DDA mass spectrometry with high-resolution, high signal-to-noise ratio (SNR), clearly annotated spectra.** Annotated spectra (i.e. spectra with the matched peaks clearly labeled) must be provided in the supplementary material for the manuscript. While low resolution and low SNR spectra can still be useful for many experiments, they are not acceptable for claims of extraordinary detections.
11. **Consider alternate explanations of PSMs that appear to implicate extraordinary results.** The spectra should be examined closely to determine if there are peaks missing that should be expected, if there are peaks present that are unexplained, and if a small alteration of the putative sequence would yield a much better match. This may indicate a false positive of a kind that is not modeled well by decoys.
12. **Present annotated spectra for extraordinary detection claims alongside high-resolution, high-SNR, clearly annotated spectra of synthetic peptides that match the putative identifications.** Synthetic peptides are powerful tools for determining the correct identification of spectra. For each PSM corresponding to an extraordinary detection claim, a synthetic peptide should be ordered and run through the same high resolution instrument to verify that the intensity patterns of the spectra and the retention times are a very close match.
13. **If SRM verification for extraordinary detection claims is performed, present target traces alongside synthetic heavy-labeled peptide traces, demonstrating very closely matching elution time and intensity patterns.** All SRM runs performed must have spiked-in heavy labeled peptides corresponding to the putative identifications. Annotated chromatograms must be provided in the supplementary material for the manuscript. Remember that solid peptide sequence evidence does not alter the uncertainties in matching that peptide uniquely to a protein (guideline 14).
14. **After very high confidence peptide identifications are demonstrated, consider alternate mappings of the peptide to proteins other than the claimed extraordinary result. Consider isobaric sequence/mass modification variants, all known SAAVs, and even unknown SAAVs.** Even when a peptide identification is shown to be very highly confident, care should be taken when mapping it to a protein or novel coding element. Consider whether I=L, Q[Deamidated]=E, GG=N, Q≈K, F≈M[147], or other isobaric or near isobaric substitutions could change the mapping of the peptide from an extraordinary result to a mapping to a commonly-observed protein. Consider if a known single amino-acid variation (SAAV) in neXtProt could turn an extraordinary result into an ordinary result. Consider if a single amino-acid change, not yet annotated in a well-known source, could turn an extraordinary result into a questionable result. Check more than one reference proteome (e.g., RefSeq may have entries that UniProt and Ensembl do not, and vice versa).
15. **Support extraordinary detection claims by two or more distinct uniquely-mapping peptide sequences of length ≥9 AA. When only lesser evidence is offered for an extraordinary protein or coding element detection, justify that other peptides cannot be expected.** Single-peptide detections simply have too high a chance of being some type of pernicious false positive to be sufficient for claiming an extraordinary result. Likewise, short peptides of length 8 or smaller have relatively few peaks and have an increased chance of mapping to immunoglobulins or other sequences not readily apparent in the reference proteome. In rare cases only a single uniquely mapping peptide can be reasonably expected even when applying different proteases; this may then be sufficient if the case is well justified. Alternatively, if it is desirable to present evidence that does not meet these criteria for extraordinary claims, the implicated proteins may be offered as “candidate detections” to enable capture of this information by other researchers for follow up by further experiments.
